## EXPERIMENT 1

### Implementation of Lexical Analyzer

**Aim:** Write a program in C/C++ to implement a lexical analyzer.

**Algorithm:**

1. Start
2. Get the input expression from the user.
3. Store the keywords and operators.
4. Perform analysis of the tokens based on the ASCII values.
- 5.

ASCII Range	TOKEN TYPE
97-122	Keyword else identifier
48-57	Constant else operator
Greater than 12	Symbol

6. Print the token types.
7. Stop

**Program (lexi.c):**

```

## EXPERIMENT 7

### Computation of Shift Reduce Parsing

**Aim:** Write a program in C/C++ to implement the shift reduce parsing.

**Algorithm:**

1. Start the Process.
2. Symbols from the input are shifted onto stack until a handle appears on top of the stack.
3. The Symbols that are the handle on top of the stack are then replaces by the left-hand side of the production (reduced).
4. If this result in another handle on top of the stack, then another reduction is done, otherwise we go back to shifting.
5. This combination of shifting input symbols onto the stack and reducing productions when handles appear on the top of the stack continues until all of the input is consumed and the goal symbol is the only thing on the stack - the input is then accepted.
6. If we reach the end of the input and cannot reduce the stack to the goal symbol, the input is rejected.
7. Stop the process.

**Program (srp.cpp):**

```
#include<stdio.h>
#include<string.h>

The screenshot shows the Visual Studio Code interface with a C program named 'practical9CD.c' open. The code defines a function 'main' that takes a string 'x' and prints a table of operations. The terminal output shows the program's execution, including prompts for string input and the resulting output table.

## **EXPERIMENT 10**

### **Intermediate Code Generation**

**Aim:** Write a program in C/C++ to generate intermediate code from a given syntax tree statement.

**Algorithm:**

1. Start the process.
2. Input an expression EXP from user.
3. Process the expression from right hand side to left hand side.
4. FLAG:=0; TOP = -1;
5. IF EXP = '=' then
  - i. IF EXP(index - 1) = 0 then
    1. PRINT EXP element from index to (index - 1) and POP STACK[TOP]. Terminate
  - Else
    - i. PRINT Wrong Expression
- [EndIF]
- IF an operator is found and FLAG = 0 then
  - i. TOP:= TOP + 1
  - ii. add to STACK[TOP].
  - iii. FLAG:=1
- Else
  - i. pop twice the STACK and result add to the newID(identifier) and PRINT.
  - ii. TOP:=TOP-2. Save newID to STACK[TOP]
  - iii. FLAG:=0
- [EndIF]
6. IF an operand is found then
  - i. TOP:=TOP+1
  - ii. move to STACK [TOP]
  - iii. IF TOP > 1 then
    1. pop twice the STACK and result add to the newID(identifier) and PRINT.
    2. TOP:=TOP-2. Save newID to STACK[TOP]

## OUTPUT:

The screenshot shows a web browser window with the URL `onlinegdb.com/online_c++_compiler`. The browser tabs include 'Online C++ Compiler - online...', 'Practical-8', and 'Program-8 - Google Docs'. The compiler interface has a top bar with buttons for 'Run', 'Debug', 'Stop', 'Share', 'Save', and 'Beautify', along with a 'Language' dropdown set to 'C++'. The code editor displays a C++ program in `main.cpp` with the following code:

```
55 push(*e);
56 }
57 e++;
58 }
59 while(top != -1)
60 {
61 printf("%c", pop());
62 }
63 return 0;
64 }
65
```

Below the code editor is an 'Input' section with the text 'Enter the expression:a+b-c' and the input 'ab+c-'. The output section shows the message '...Program finished with exit code 0' and 'Press ENTER to exit console.'.

**Result:** The Program Executed successfully
